

Orbit Analytics - Product Manual

Administrator guide for Orbit Analytics 5.1.

1. Installation

Orbit Analytics requires Python 3.11 or newer, 8 GB of RAM and 20 GB of free disk space on the application server.

Installation is performed with the command 'orbitctl install --profile production'. The installer writes its configuration to /etc/orbit/orbit.yaml.

The first administrator account is created by running 'orbitctl admin create'. The command prints a one time setup token that expires after 60 minutes.

2. Dashboards

A dashboard may contain at most 24 widgets. Widgets are refreshed every 5 minutes by default; the refresh interval can be lowered to 1 minute on the Enterprise plan.

Dashboard definitions can be exported as JSON and imported into another workspace. Scheduled exports run daily at 06:00 local time.

Deleting a dashboard moves it to the trash, where it is retained for 90 days before permanent removal.

3. API and Limits

The REST API is rate limited to 600 requests per minute per API key. Requests above the limit receive HTTP 429 with a Retry-After header.

A single API request may return at most 1000 records. Larger result sets must be paginated with the cursor parameter.

API keys expire after 365 days and must be rotated before expiry. Each workspace may hold a maximum of 10 active API keys.

4. Backups and Retention

Automated backups run every 6 hours and are retained for 35 days.

Point in time recovery is available for the previous 7 days on the Enterprise plan and the previous 24 hours on the Standard plan.

Restoring a backup requires the maintenance window to be scheduled at least 48 hours in advance.
